

CSCE 451 Assignment 2:

REMOTE SHELL USING SOCKET PROGRAMMING

100 points

This assignment consists of writing a C program for a remote shell system. It involves a Server and a Client process. The server process resides on another machine on the network and the user provides commands to the server via a client process on a local machine. The client will connect to the server then it will start sending the commands to the server, the server executes them, and sends the output back to the client.

The goal of this assignment is to practice some system calls and process management by the operating system. In addition, it reinforces the operating system support for client server programming using sockets. You will write a basic remote shell in which a user specifies an arbitrary shell command to be executed, and it is sent over socket connection and executed on a remote server.

(Note: use connection-oriented communication (socket programming using TCP))

You will write a server and a client program:

Server: The server will run on the remote machine.

- It will bind to a **TCP** socket at a port known to the client and wait for a Connection Request from Client.
- When it receives a connection, it forks a child process to handle this connection. The server will notify the client that the connection was successful, and the Server will prompt message “Client (IPDRESS: PORT#) Connected to the server successfully”.
- Client will start sending commands to the server. **The Server must handle multiple clients at a time.**
- The parent process at the server loops back to wait for more connections.
- The child process executes the given shell command (received from the client), returning all **stdout** and **stderr** to the client. (Hence, **the server will not display the output of the executed command**)
- The server can assume that the shell command does not use **stdin**.

Client: The client will run on the local machine.

- From the command line, the user will specify the host (where the server resides) and the command to be executed.
- The client will then connect to the server via a TCP socket.
- Once Connected, the Client will prompt message “Connected to the server (IPDRESS: PORT#) successfully”.
- The client sends the command to the server.
- The client will display any output received from the server to the **stdout**.
- After displaying the output, the client waits for next command from the user.
- The client will **not** close/exit until the user enters “**quit**” command.

Creating a Child Process

At Server side, for each incoming client, a child process is forked which executes the command received from the client.

The separate child process is created using the `fork()` system call, and the user's command is executed using one of the system calls in the `exec()` family.

Note:(The example below is one way of doing this, you are welcome to do it your own way!)

This will require parsing the command into separate tokens and storing the tokens in an array of character strings, say **args**. For example, if the command entered at the prompt is:

ps -ael

the values stored in the args array are:

`args[0] = "ps"`

`args[1] = "-ael"`

`args[2] = NULL`

This args array will be passed to the `execvp()` function, which has the following prototype:

`execvp(char *command, char *params[]);`

Here, `command` represents the command to be performed and `params` stores the parameters to this command. For this assignment, the `execvp()` function should be invoked as `execvp(args[0], args)`.

Remember: In this assignment, the command is entered on Client!

Submission

- You should use C to develop the code.
- You should work on this project **individually**.
- You need to turn in electronically by submitting a zip file named: `Lastname_Firstname_Assignment3.zip`.
- **Source code must include proper documentation to receive full credit (you will lose 10% of your score, if the code is not well documented).**
- All Assignments require the use of a **make file** (accompanying with a **readme file** to specify how to use make file to compile), such that the grader will be able to compile/build your executable by simply typing "make" or some simple command that you specify in your readme file.
- **Source code must compile and run correctly on "https://cse-linux-01@unl.edu", which will be used by the TA for grading. If your program compiles, but does not run correctly on cse, you will lose 50% of the assignment score. If your program doesn't compile at all on cse, you will lose 100% of the assignment score.**

- You are responsible for thoroughly testing and debugging your code. You can have multiple submissions, but the TA will grade only the last one.

Start as early as possible!

Some Details on Shell:

A shell interface gives the user a prompt, after which the next command is entered. The example below illustrates the prompt **osh>** and the user's next command: **cat prog.c**. (This command displays the file **prog.c** on the terminal using the UNIX **cat** command.)

osh> cat prog.c

One technique for implementing a shell interface is to have the parent process first read what the user enters on the command line (in this case, **cat prog.c**), and then create a separate child process that performs the command.

A C program that provides the general operations of a command-line shell is supplied in Figure 1. The **main()** function presents the prompt **osh->** and outlines the steps to be taken after input from the user has been read. The **main()** function continually loops as long as **shouldrun** equals 1; when the user enters "quit" at the prompt, your program will set **shouldrun** to 0 and terminate.

```
#include <stdio.h>
#include <unistd.h>
#define MAX LINE 80          /* The maximum length command */
int main(void)
{ char *args[MAXLINE/2 + 1]; /* command line arguments */
  int shouldrun = 1;          /* flag to determine when to exit program */
  while (shouldrun) {
      printf("osh>");
      fflush(stdout);
  /**
  After reading user input, the steps are:
  (1) fork a child process using fork()
  (2) the child process will invoke execvp()
  */
  } return 0; }
```

Figure 1 Outline of simple shell.
